ECM Connector

NOTE: all components listed above are included in the ETC throttle body assembly. These components are not individually serviceable and would require the whole assembly to be replaced in the event of a service repair being required by an individual component failure.

ETC System Description

What is electronic throttle control?

- A throttle body is traditionally controlled through mechanical linkages connected to a mechanically sprung governor control system. Electronic throttle control (ETC) now uses the ECU to control the throttle body electronically rather than mechanically. Many functions are associated with an engine's throttle body and mechanical governor system. ETC now uses a control module that offers the same functions electronically to improve engine performance, starting performance, speed control, load response and more.

What is an electronic governor?

- Electronic governor (E-Gov) systems are often incorrectly used to describe electronic throttle control. Electronic governing is a function that is controlled by the ETC system that involves engine speed, load response and stability control. Other functions and benefits of ETC would fall outside of the E-Gov feature.

How does engine performance change?

- The use of ETC can improve the amount of usable power being produced by the engine due to the reduction in governor droop. The engine's response to load acceptance can also be improved and reduce the impact of speed overshoot or undershoot.

-

- **Direct Throttle (WOT) horsepower curve** – this is identified by the blue dotted power curve in Figure 1. Peak horsepower occurs at maximum engine operating speed noted by the orange arrow in Figure 1.

- **Mechanically controlled throttle body system** – this is identified by the solid red line in Figure 1. Peak horsepower occurs where the governor droop meets the power curve and is noted by the red arrow in Figure 1. A shallow droop curve slope and rolling transition to the power curve limit the overall performance and response of the mechanical system.

- **Electronically controlled throttle body system** – This is identified by the black dashed line in Figure 1. Peak horsepower occurs where the ETC's governor calibration transitions to the power curve and is identified by the green arrow in Figure 1. The governor calibration allows for a much tighter droop curve slope which translates into higher peak power availability. The steeper slope and quicker transition to the power curve also provide quicker and more stable load acceptance. The green dashed area on Figure 1 represents the additional "usable" power the ETC will offer over a traditional mechanical controlled system.
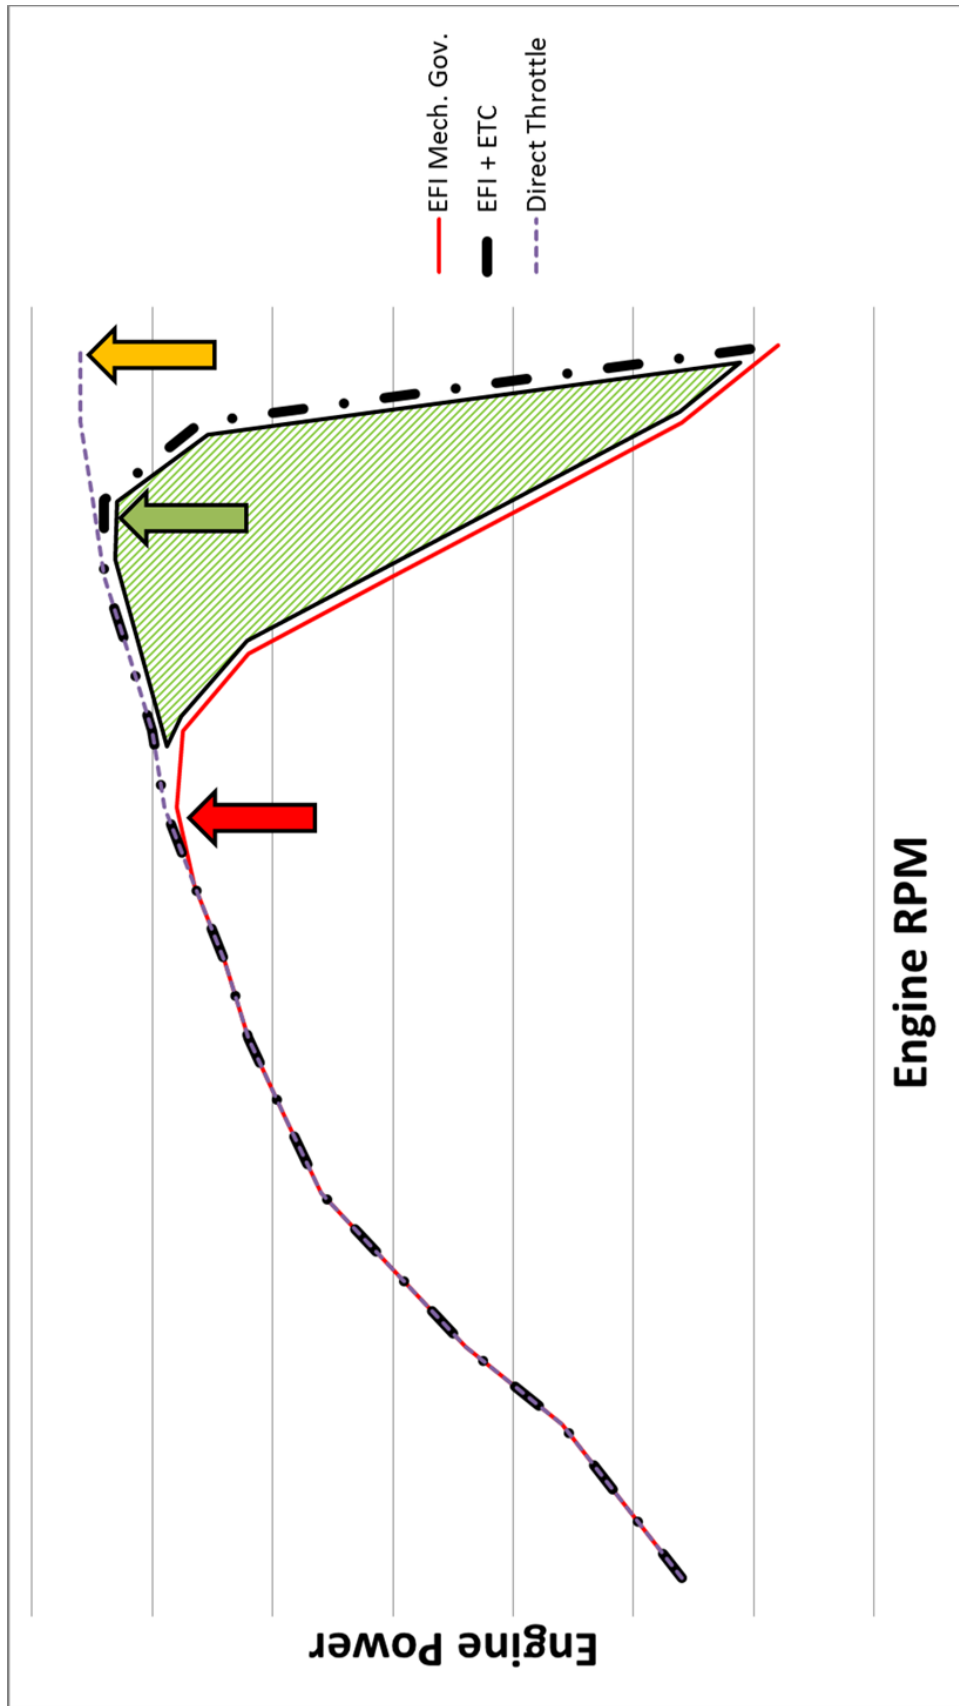

Figure 1: Direct Throttle vs. Mech. Gov. Droop vs. ETC Droop

Operating Temperature Compensation

Ignition Timing vs. Cylinder Head Temperatures – based on the measured cylinder head temperatures the desired ignition timing can continuously change to improve engine operating. The calibration strategy begins to retard timing as cylinder head temperature trends warmer.

Overheat Strategy – This will not begin to control the engine until cylinder head temperatures have exceeded 180 deg. C. Once the overheat strategy has been triggered there are throttle angle, ignition timing and air/fuel ratio compensations employed to reduce engine power output and cool the engine.

ETC Cold Start Strategy

One key feature of ETC is the improved cold start capabilities. If the engine cylinder head temperature is below a calibrated set point then additional engine speed will be commanded. This is done in an effort to improve cold engine stability and decrease the engine warm up time. Once the engine has met the necessary criteria the ECM will exit the cold start strategy and command idle at the base engine speed. Please note the engine will not exceed the maximum calibrated RPM for high speed. The cold start strategy only applies additional RPM at or near low idle.
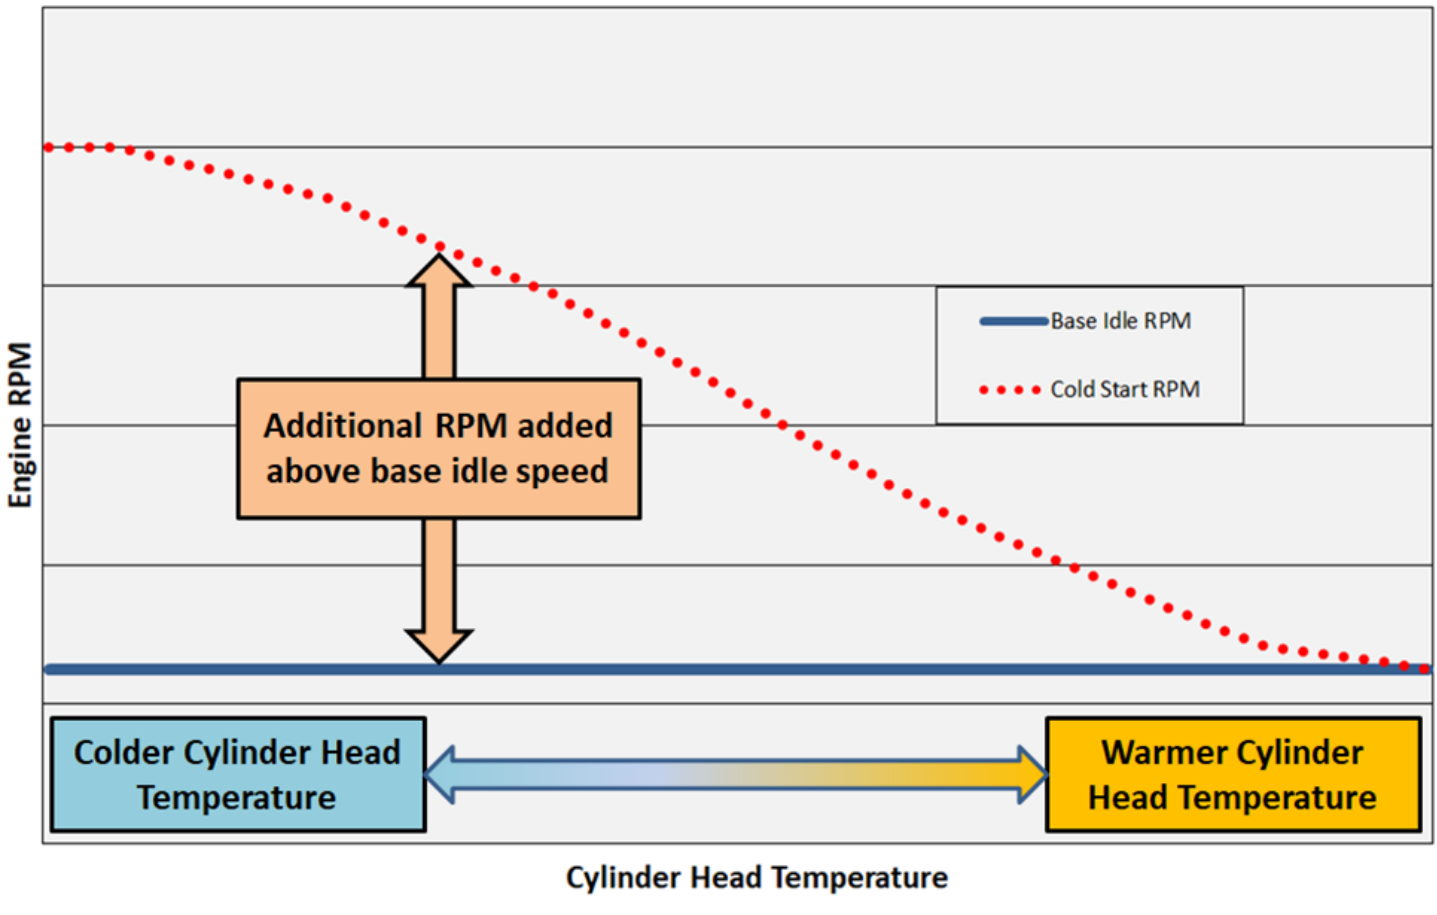

Understanding ETC Governor Overshoot and Undershoot

A governor system is in equilibrium when the engine speed output equals the target engine speed to complete the chore being performed by the application. When the target speed to complete the chore has changed the engine governor must change the engine speed output to accommodate the increase or decrease in target speed. (See Figure 2)

- **Overshoot** occurs when the engine governor responds rapidly and engine speed will momentarily exceed the target speed and fail to achieve equilibrium. The engine speed can have multiple recovery oscillations to achieve equilibrium depending on the ETC calibration parameters.

- **Undershoot** can occur due to slow response time or as a response to overshoot.
    - Slow response undershoot occurs when the engine fails to meet equilibrium quick enough. This type of undershoot is defined by the time the engine speed is below the target engine speed beyond the ideal stabilization point.
    - Fast response undershoot happens after engine speed has first seen an overshoot condition. The engine will respond to overshoot by quickly reducing engine speed lower than the target speed. The engine speed can have multiple recovery oscillations to achieve equilibrium depending on the ETC calibration parameters.

- An **ideal stabilization point** is the best response possible to complete the chore while providing the application operator with a satisfying physical and audible experience. ETC response time can vary with the amount of overshoot, undershoot and speed oscillations being calibrated to operator preferences in an effort to achieve a balance between performance and comfort.

Recommended Pin Connection Details

Pin 1 = Open / Not Used

Pin 2 = CAN High – See details in the *CAN Control* section of *ETC Engine Speed Control Strategies* below.

Pin 3 = Analog Sensor Ground – See details in the *Analog Control* section of *ETC Engine Speed Control Strategies* below.

Pin 4 = Analog Sensor Output – See details in the *Analog Control* section of *ETC Engine Speed Control Strategies* below.

Pin 5 = Analog Sensor Power – See details in the *Analog Control* section of *ETC Engine Speed Control Strategies* below.

Pin 6 = Interlock – active low input used by application to command engine shut down.
- Grounded = engine shut down.
- Open = engine running.

- Details = input has an internal 1.62kΩ Pull-Up Resistor with series diode.

Pin 7 = Ignition Power – Apply battery voltage to this pin to turn on engine ECM.
- Battery voltage is applied to this input to turn the ECU on so the engine can be started.

Pin 8 = Battery / EFI Power – Used to power EFI system from application.
- This connection will be connected to battery positive (+) terminal.
- This must be unswitched.

Pin 9 = Harness dependent – Regulator OR Open / Not Used – Can be used to charge the battery if from voltage regulator if populated in the connector.
- This connection will be connected to battery positive (+) terminal.
- This connection can be used to test the charging system.

Pin 10 = CAN Low – See details in the *CAN Control* section of *ETC Engine Speed Control Strategies* below.

Pin 11 = Brake Switch – Programmable input used by the application to change engine operation.
- Active with low circuit.
- Test stand should ground this pin during test and look for status change on the CANBUS.
- Switch configurable in software.
- This input has an internal 432Ω Pull-Up Resistor with series diode.

Pin 12 = Open / Not Used

Pin 13 = MIL – This pin is connected to ground when an engine fault is active.
- Maximum sink current = 1A.
- Recommended customer supply current limiting resistor if LED is used.
- Recommended to connect to ignition power.

Pin 14 = Tach Output – this output is used to drive a tachometer.
- One pulse is created per one engine crankshaft revolution.
- Tach signal is 0 to 12 volts.
- This output has an internal 1.62kΩ Pull-Up Resistor.
- Max output power at 12.5V = 7.7mA.
- Max sinking current is 50mA.

Pin 15 = Harness dependent – Starter Solenoid OR Open / Not Used – Can be used to pass a start signal from the vehicle harness through the engine connector to the starter solenoid.
- This is a low current circuit connected to battery positive (+) to trigger the starter solenoid.

Pin 16 = Open / Not Used

Figure 9: 20/50 amp alternator curve

Electrical protection:

- Electric clutch manufacturers recommend that a 24 volt zener diode be placed across the power and ground lead near the clutch to reduce voltage spikes upon clutch disengagement. Diode part 5100781 may be used.
- EFI electronics are very sensitive to voltage and current spikes.
    - Batteries must not become disconnected from system during operation of engine.
    - Some Lithium Ion starting batteries contain special electronics that disconnect the charge system when the battery determines it no longer needs charge. Verify that the style of lithium battery used does not create this situation.
- Wiring should be protected from heat sources and sharp edges. The length of wire used should be sufficient to prevent stressing wires and connections.

CAN Communication Capability

The EFI+ETC system implemented on these engines uses a Controller Area Network (CAN) communication strategy. This opens many doors to equipment manufactures for controlling and monitoring the engine state during operation.
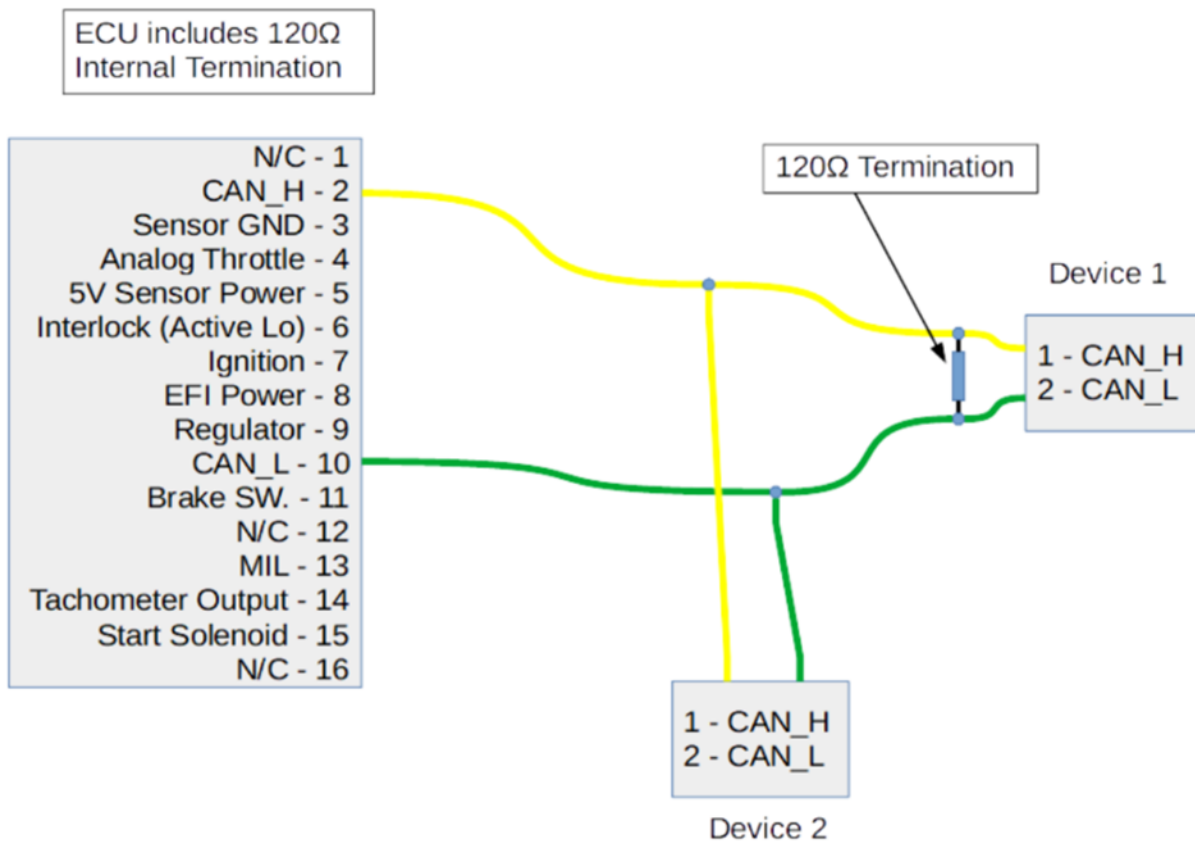

Figure 10: CAN Wiring

CANBUS Details

- CAN specification = SAE J1939
    - Baud Rate = 250 Kbit/s
    - Appendix A: PGN & SPN list sent by ECM (Broadcast)
    - Appendix B: PGN & SPN list received by ECM (Respond to)

- Recommend 1.5 twists per inch for CAN wires
- Throttle body includes a terminating resistor. It is recommended that remote CAN connections include terminating resistors.
    - A maximum of (2) terminating resistors are allowed in the system. Having more terminating resistors in the system can disrupt the CANBUS signal.
    - It is recommended that the terminating resistors are placed at either end of the signal. Briggs included at throttle body and OEM included at controller.
- Control engine speed – see details below

ETC Engine Speed Control Strategies

Analog Control – 5 volt sensor power and sensor ground can be used with customer supplied hall-effect throttle sensor input to control engine speed. Analog control is established using engine connector pins 3, 4 and 5 as shown below. This method allows for an infinite sweep of engine speeds to mimic a cable throttle seen on mechanically governed engines.
Figure 11: Analog controller wiring

Electrical Characteristics
- Input has an internal 10 kΩ pull-p resistor
- 5V sensor power can source a maximum current of 50mA
- Throttle input accepts 0-5V
  - 0.0 to 0.1 Volts – Diagnostic/Fault Low Voltage Region – ECM commands Idle
  - 0.1 to 1.0 Volts – Deadband
  - 1.0 to 4.0 Volts – Linear Region
  - 1.0 Volts – Idle (Speed Calibration Dependent)
  - 4.0 Volts – High Speed – No Load (Calibration Dependent)
  - 4.0 to 4.9 Volts - Deadband
  - 4.9 to 5.0 Volts – Diagnostic/Fault High Voltage Region – ECM commands Idle
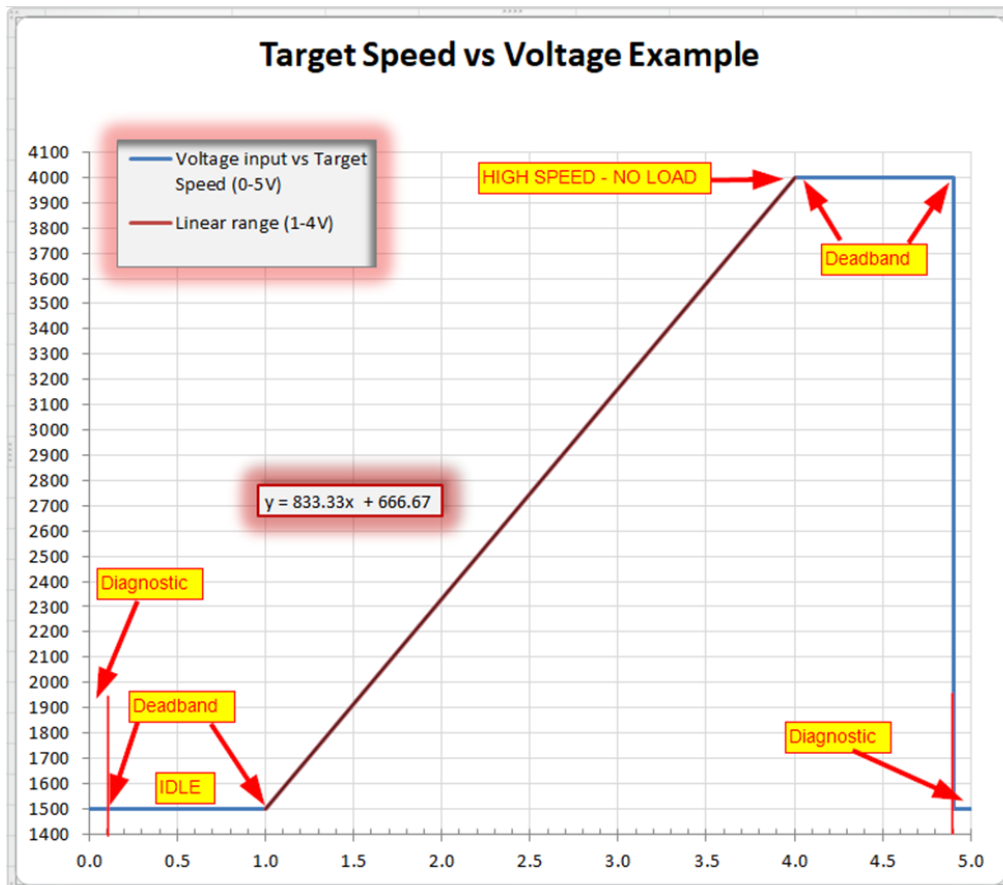

CAN Control – a customer supplied CAN capable controller can be used to communicate engine speed commands to the engine ECM. (NOTE: CAN commanded cranking/starting is not available.)

** Customer must submit controller spec. to assure compatibility with B&S J1939 CAN based ECM**

CAN Controlled Engine Speed Options and Limits
- The equipment manufacture will set the operating range of the engine for their specific application within the boundaries available with CAN speed control.
    o   Minimum Low Speed = 1200 rpm
    o   Maximum High Speed = 4000 rpm (3800 rpm on the 33 hp)
- CAN speed control messaging details – in order for OEMs to control speed through the CANBUS they will need to utilize the Torque/Speed Control #1 (TSC1) PGN. Please see the PGN details below for controlling engine speed.
    o   TSC1 recommended update rate = 20 msec.

3.5.2   PGN 0 – Torque/Speed Control #1

Engine speed can be set with this PGN. Minimum SPNs needed for engine speed control include: 898, 3349, 4206, and 4207.

Part of the PGN	Value	Remarks
Transmission Repetition Rate	Control Purpose Dependent – Maximum 10 ms	
Data Length	8 bytes	
Extended Data Page	0	
Data Page	0	
PDU Format	0	
PDU Specific	218

Figure 14: TSC1 SPN Detail

Exhaust System

Maximum backpressure limits are engine dependent. Consult Application Engineering / PAC
OEM supplied mufflers must be reviewed for back pressure compliance

Mounting Boss Dimensions

Mounting Boss: M12 x 1.25 – 6G Threads

Major Diameter: 12.388 – 12.028 mm

Minor Diameter: 10.940 – 10.675 mm

Pitch Diameter: 11.396 – 11.216 mm

Material: Ferritic Stainless Steel or equivalent

Thread Quality: Threads must be free of burrs, voids, or other imperfections which would interfere with proper installation or removal of the sensor.

Boss Thickness: 7.0 – 7.4 mm

Sealing Surface Roughness: 3.2 RMS

Leakage: less than 5scc per min @ 3psi on fresh application
Figure 16: Acceptable O2 sensor orientation

- O2 sensors must be placed in the first chamber where cylinder 1 and 2 exhaust gases are combined. The sensor must also be placed as far from the exhaust outlet as possible.
- O2 sensors must be installed dry. **DO NOT USE LUBRICANT OR ANTI-SIEZE ON THREADS**.

Fuel System

Lift Pump
- Operating voltage range = 8.5-16V
- Max operating current = 1.5A
- Lift height maximum: 18 inches (dry pump) ● Output pressure is 2.5 to 3.3 psi (17-23kPa) at 0 delivery.
- Runs for 2 seconds upon turning the key "on". (If the key switch is cycled from on-off-on the pump will not run unless the key switch is off for 10 seconds).

High Pressure Module
- Max operating current = 2A
- Pressure output to injectors = 38-43 PSI

Fuel Filter - 30 micron installed on the engine. Filter fuel before the lift pump.
